## Alabama Daily Temperature Normals

Rodger Getz<sup>1</sup>

Climatic data is often needed by business people, government workers, researchers, etc., to compare present weather with past weather. This data is particularly important in assessing the present weather conditions on crops, energy use, animals, man, and many industrial operations.

This publication presents in table form the mean daily temperatures for 38 Alabama observation stations (Fig. 1). The daily mean temperatures were computed in accordance with a technique devised by Greville (1). By this technique, instead of averaging daily maximum and minimum temperatures over a period of years to get a mean, daily means are computed using a 30-year sequence of monthly mean values. This technique is recognized by, and in general use by the National Climatic Center of the United States Department of Commerce in computing daily normals for first order National Weather Service Stations (2). The monthly mean temperatures used for this computation were extracted directly from the Alabama section of Climatology of the United States No 81 (3).

The locations of the stations for which means have been computed are shown in figure 1. The tables are in alphabetical order. To use the tables, locate at the top of the columns the month. Locate at the extreme left or right the day of the month. Follow down the column under the month, and across from the day; at the intersection of these two will be found the mean temperature for the day. On leap year, use the value for February 28 for the 29th day. Monthly and annual normals are listed at the bottom of each page.
