# **PERFORMANCE OF SOYBEAN VARIETIES IN ALABAMA, 1994**

**K.M. Glass and D.I. Bransby<sup>1</sup>**

## **INTRODUCTION**

Soybean variety tests are conducted annually by the Alabama Agricultural Experiment Station. The seven locations used represent the major soil and climatic regions of Alabama. These locations are divided into logical soybean growing regions. The regions and locations are:

| <b>Region</b> | <b>Location</b>             |
|---------------|-----------------------------|
| Northern      | Belle Mina, Crossville      |
| Central       | Prattville                  |
| Southern      | Brewton, Monroeville        |
| Black Belt    | Marion Junction (two soils) |
| Gulf Coast    | Fairhope                    |

## **EXPERIMENTAL PROCEDURES**

The standard tests were designed as a randomized complete block with four replications. Plot size was four 24- to 36-inch rows 20 feet long. Sixteen feet of the middle two rows were harvested for yield. Seeding rate was 10 viable seeds per foot of row. The early date test was arranged in an incomplete lattice square design with four replications.

Data were collected on seed yield, moisture, lodging, shattering, plant height, and maturity date. Plot yields were adjusted to 13 percent moisture and converted to bushels (60 pounds) per acre.

---

<sup>1</sup>Research Assistant and Professor of Agronomy and Soils.

Lodging was scored on a scale of 1 to 5 as follows:

*1 - almost all plants erect.*

*2 - either all plants leaning slightly (less than 45 °) or a few plants down.*

*3 - either all plants leaning moderately (approximately 45 °) or 25 to 50 percent of the plants down.*

*4 - either all plants leaning more than 45 ° or 50 to 80 percent of the plants down.*

*5 - more than 80 percent of the plants down.*

Shattering was rated on a scale of 1 to 5 based on performance of the border row 14 days after maturity. A rating of 1 indicates no shattering, a rating of 3 indicates a 4 to 8 percent shattering, and a rating of 5 is 20 percent or more shattering. Plant height was determined by measuring from the ground to the top of the plant at maturity. Maturity date was the day 95 percent of the pods reached mature pod color. Harvest was approximately 7 to 10 days later.

#### **SEASONAL CONDITIONS**

Rainfall (Table 3) in April and May 1993 and 1994 was such that planting dates for the standard tests in northern Alabama and Marion Junction and Prattville in central Alabama were delayed. All other standard tests were planted for optimum growth. The normal planting dates for full season plantings in the regular tests are the first week in May, May 15-25, and May 25 to June 5 for northern, central, and southern Alabama locations, respectively.

The Sumter soil test at Marion Junction was not reported due to excessive herbicide damage.

## COMPARING VARIETIES

To aid in determining real yield differences, a statistical analysis of variance is performed on the data from each location. The L.S.D. (least significant difference) and C.V. (coefficient of variation) are given for each location's 1994 test, and for the location's or region's 2- and 3-year averages. The difference in yield of two varieties must exceed the L.S.D. value for one variety to be considered superior to the others in yield in that particular test. The C.V. is a measure of the variability in an experiment. An increase in its value indicates an increase in the unexplained variability.

Since the performance of varieties varies with location and year, long-term averages from several locations are more reliable than 1-year performance. Three-year regional averages are considered a reliable evaluation of the relative performance of varieties.

## ACKNOWLEDGMENTS

Appreciation is expressed to the following station superintendents and their staffs. It is their quality work which makes this report a reliable source of information for farmers in their areas.
