Tables for Computing Relative Conditions of Some Common Freshwater Fishes

W. E. SWINGLE and E. W. SHELL¹

INTRODUCTION

THE TABLES presented in this publication were compiled from length-weight measurements of fishes collected during a 15-year period from Alabama rivers and river impoundments by use of rotenone.² Data were stratified so that no year or river system was more heavily weighted than the others. These tables allow the biologist to rapidly compare the conditions of fish by computing the relative condition factor of LeCren³, which is expressed as follows:

$$Kn = \frac{W}{\hat{W}}$$

where W equals the weight of a fish of a specific length and \hat{W} is the computed weight for the same length, derived from the equation $\hat{W} = aL^b$, for this species in Alabama river systems.

The \hat{W} values are those given in the tables for the specific length of a species.

Lagler⁴ suggested the use of an index of condition of the form $C = WX10^5/L^3$ in preference to Kn . This results in each species having condition indices that form a range of arbitrary numbers

that vary greatly from species to species and gradually for different sizes of the same species. For example, taking C values from Swingle² for 10-inch paddlefish, largemouth bass, and small-mouth buffalo, the respective values were 8.2, 45.0, and 53.3. Without standards for comparison, use of such a system of comparing condition has no real meaning. For instance, an 8-inch bass weighing 0.24 pound would have C of 46.87, ($C = 0.24 \times 10^5/8^3$). Of itself, this figure is less valuable than the two parameters from which it was derived. One could compute the length-weight equation $W = aL^b$ for a number of populations and learn that the average weight for 8-inch bass derived from this equation was 0.23 pound. It is then obvious that the 0.24-pound bass is in slightly better condition than the average. However, to quantitate the C value in relation to the average, a C must be computed using the average weight, 0.23 pound, giving a value of 44.92, ($C = 0.23 \times 10^5/8^3$). Thus one now has two values of condition, 46.87 for the individual fish and 44.92 for the population average. To express the degree by which the condition of the individual is better than the average, it would seem logical to compute the following ratio 46.87/44.92, which equals 1.043. This value then indicates that the C value for the individual is 1.043 times the C value for the population average. However, if one had computed the Kn value, he would have $Kn = 0.24/0.23 = 1.043$. Thus the use of Kn for the measurement of condition of a fish results in a value that has a common base regardless of species or size. Kn is always 1.0 when the condition or weight of an individual is equal to the average condition or weight for a specific length. Whenever fish are in poorer condition than average, Kn is less than 1.0, and when condition is better than average Kn is greater than 1.0. For example, respective Kn values of 0.8 and 1.2 for two fish of the same length would indicate that the second weighs 50 per cent more than the first and 20 per cent more than the average or base.

The computation of relative condition factors has provided useful information in a variety of situations. Biologists in Florida have used Kn values in a hatchery to detect heavy parasite infestations in largemouth bass. Bass being cultured in ponds had Kn values averaging about 1.2. At a later date, Kn values dropped below 1.0 and examination of the fish showed them to be heavily parasitized. It may be useful to routinely determine Kn values for broodstock and examine or discard those in poor condition.

² *Ibid.* p. 3.

The following values were computed for an unbalanced bluegill population:

Inch-group	3	4	5	6	7
Kn	0.55	0.33	0.76	0.84	0.68

Not only is it evident that the whole population is crowded, but also that crowding is worse in the 4-inch group.

It has been demonstrated that the condition of fish varies with season, sex, and population. This is illustrated in Tables 1 and 2. Therefore, if a different \hat{W} value is computed during each season, the Kn values derived are not comparable. However, acceptance of standard \hat{W} values, such as are provided in the tables, makes Kn values comparable.

Table 1 gives the relative conditions of male bluegill in populations from two ponds with feeding and one with inorganic fertilization during the spring, summer, fall, and winter. These values were computed by measuring the fish in millimeters and grams and computing a Kn value for each fish using \hat{W} from the tables and averaging the Kn values for all fish in each inch-group. These data show that the bluegills were in the best condition in the summer and the poorest in the winter. The bluegills that received supplemental feed were in better condition than those in the fertilized pond, and both fed and fertilized populations were in better condition than bluegills from the natural waters of Alabama ($Kn = 1.0$). It appears from the data that 4- and 5-inch fish better utilized food organisms produced by fertilization, while all the fish larger than the 4-inch group utilized the pelleted feed.

Table 2 presents the relative conditions of male and female bluegills from fed, fertilized, and natural populations in the fall. Lake Eufaula and Lake Martin are both on rivers that drain the infertile soils of the Piedmont Plateau; therefore, the condition of the bluegills would be expected to be slightly below the state average ($Kn = 1.0$). Lake Eufaula is a fairly new impoundment, while Lake Martin is quite old, and the former receives more domestic sewage than the latter. These factors perhaps account for the better conditions of Eufaula fish. Also it should be noted that there was little difference between the conditions of male and female bluegill from the natural populations, while the male bluegill from both fed and fertilized populations were in better condition than the females.

The use of Kn will probably have its greatest application in

studies of fish populations of reservoirs and other natural waters. Swingle and Swingle⁵ found that rotenone sampling was not effective in detecting fluctuations in year-class abundance of such species as crappie, even though these fluctuations were known to be occurring. However, yearly determination of Kn values for all sizes of crappie should indicate which groups were crowded or most abundant. Similarly, the condition of other species could be monitored and these data used with other sampling data to more accurately determine the status of a species within the total population. Theoretically, when data on the condition of the various sizes of each species within a population had been accumulated over many years and a norm established for a body of water, then any deviation from the norm would indicate some fluctuation taking place within the population or some physical or chemical condition interacting with some segment of the population.

Relative conditions would also appear useful in detecting pollution or any condition that results in prolonged physiological stress on a segment of a fish population.

The tables of length-weight values for each species are arranged in alphabetical order by common name. The length used was total length. Conversion tables for inches-millimeters and grams-pounds are in the Appendix.

In the index to species, the arrangement is alphabetical using the common names of species followed by their scientific names as listed by the American Fisheries Society. One exception is *Cyprinus carpio*, which is listed as the common carp in accordance with world-wide usage. This is the scaled variety found in rivers and impoundments.

AGRICULTURAL EXPERIMENT STATION SYSTEM OF ALABAMA'S LAND-GRANT UNIVERSITY

With an agricultural research unit in every major soil area, Auburn University serves the needs of field crop, livestock, forestry, and horticultural producers in each region in Alabama. Every citizen of the State has a stake in this research program, since any advantage from new and more economical ways of producing and handling farm products directly benefits the consuming public.

Research Unit Identification

★ Main Agricultural Experiment Station, Auburn

1. Tennessee Valley Substation, Belle Mina.
2. Sand Mountain Substation, Crossville.
3. North Alabama Horticulture Substation, Cullman.
4. Upper Coastal Plain Substation, Winfield.
5. Forestry Unit, Fayette County.
6. Thorsby Foundation Seed Stocks Farm, Thorsby.
7. Chilton Area Horticulture Substation, Clanton.
8. Forestry Unit, Coosa County.
9. Piedmont Substation, Camp Hill.
10. Plant Breeding Unit, Talladega.
11. Forestry Unit, Autauga County.
12. Prattville Experiment Field, Prattville.
13. Black Belt Substation, Marion Junction.
14. Tuskegee Experiment Field, Tuskegee.
15. Lower Coastal Plain Substation, Camden.
16. Forestry Unit, Barbour County.
17. Monroeville Experiment Field, Monroeville.
18. Wiregrass Substation, Headland.
19. Brewton Experiment Field, Brewton.
20. Ornamental Horticulture Field Station, Spring Hill.
21. Gulf Coast Substation, Fairhope.
